

# Child Play

Ms. Goodheart wants to split her students into groups. She wants to seem fair, so her procedure is as follows:

- Line up every student along a wall
- Give each student a different number between 1 and N (the total number of her students)
- Tell them to get into groups. A student can be in a group only if all the the students in the group who were initially lined up to the student's left have larger numbers.

Her students are smart and know that the bigger the group, the better the outcome. Every group will have as many students as possible in it.

Ms. Goodheart does not want the groups to get too large, so she wants to run by her number ordering before making a decision. She would like to know just how large the biggest group will be.

In addition, she wants to show this off to the other teachers as well, so your program should be able to handle multiple cases.

## Input

Input begins with an integer on a single line, T, the number of test cases. Each test case will have two lines.

The first line will consist of a single positive integer N ( $N < 100,000$ ), the total number of students.

The second line will contain N space-separated numbers, all between 1 and N, inclusively. This is the ordering she is going to assign to her students. There will be no duplicate numbers.

## Output

Output one integer, the number of students in the largest possible group, per line per test case.

## Sample Input

```
3
4
1 2 3 4
4
4 3 2 1
4
3 2 4 1
```

## Sample Output

1  
4  
3
